The Company

GeneTex produces high quality antibodies validated through extensive research, development, and testing. Our staff and researchers have collectively earned a trusted reputation from the research community for the quality and reliability of our antibodies. The secret to our success is the complementation of scientific expertise and production mastery in our state-of-the-art laboratory and animal facility.

Our facility provides large-scale antibody production capabilities, which employ highly specific antigen affinity purification. This has facilitated the establishment of a comprehensive antibody collection covering a wide spectrum of research fields.

Because of GeneTex's extensive experience in antibody manufacturing, we are uniquely able to serve the demands of the scientific community by providing accurate technical support and reliable customer service.

DNA Modification

DNA methylation involves the chemical modification of cytosine residues (5mc) through the addition of a methyl group. This modification regulates gene expression without altering the DNA sequence, and is carried out by two classes of function-opposing enzymes: DNA methyltransferases (DNMTs) and methylcytosine dioxygenase (Ten Eleven Translocation; TETs). The methylated DNA is recognized by methyl-CpG-binding domain proteins (MBDs) which recruit chromatin remodeling protein complex to form compact, inactive chromatin, resulting in transcriptional repression. Accumulating studies have demonstrated that dysfunctional controls of DNA methylation are associated with various diseases including cancer.

Histone Code

The nucleosome core particle is the fundamental structural unit of the eukaryotic genome. It consists of a histone octamer composed of two H2A-H2B dimers and a H3-H4 tetramer wrapped by ~146 base pairs of DNA. A linker histone (*i.e.*, H1) associates with the nucleosomal dyad as well as with linker DNA on either side of the nucleosome, resulting in the formation of the chromatosome. All the core and linker histones are posttranslationally decorated, with at least 160 total modifications described to date including acetylation, methylation, phosphorylation, propionylation, citrullination, formylation, proline isomerization, butyrylation, ADP ribosylation, ubiquitylation, sumoylation, and the more recently identified glycosylation and crotonylation. These modifications are thought to impact chromatin functions by either altering chromatin packaging or through the recruitment/inhibition of specific chromatin binding factors. Thus, the combined signal from a particular collection of histone marks constitutes a "histone code" that affects gene expression or other chromatin-based functions.

Histone H3K18ac (acetyl Lys18) antibody (GTX128943)
ChIP analysis with Histone H3K18ac antibody on chromatin extract of HeLa cells.

Histone H3K27ac (acetyl Lys27) antibody (GTX128944)
IHC-P analysis with Histone H3K27ac antibody on mouse duodenum tissue.

Histone H3S10ph (phospho Ser10) antibody (GTX128116)
ICC/IF analysis with Histone H3S10ph antibody on HeLa cells.

Custom Antibody Services

Featured characteristics

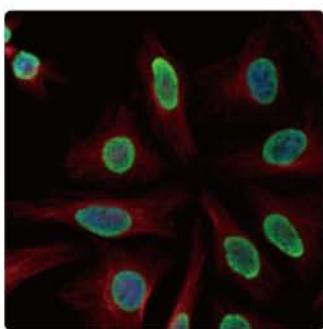

- Proprietary bioinformatics database identifies the ideal target epitope and optimizes synthesis, solubility and antigenicity
- Efficient production of high quality antigens using prokaryotic expression or peptide conjugation
- Enhanced cocktail immunization technique produces high-titer antisera
- Highly specific antigen affinity purification
- Online tracking system

Please contact us for details, pricing and if you have any questions about our custom antibody service.

Histone Modifying Enzymes - Acetylation

Acetylation is one of the most intensively studied posttranslational modifications (PTMs) of histone and non-histone substrates. For histones, members of the three major subfamilies of histone acetyltransferases (HATs; but also referred to as lysine acetyltransferases (KATs)) target lysine residues for transfer of an acetyl group obtained from acetyl-CoA. Histone acetylation is generally associated with gene activation, while histone deacetylation catalyzed by histone deacetylases (HDACs/KDACs) is linked to gene repression. The dynamic interplay between the activities of the HATs and HDACs, in conjunction with the histone marks inserted by other histone modifying enzymes, determines the key features of the local chromatin landscape that regulates a specific gene's expression. HDAC inhibitors have generated much interest clinically, particularly in cancer therapeutics. However, there is also growing awareness of "histone code" signatures that control gene expression in post-mitotic neurons, thereby affecting neural plasticity and complex higher-order brain functions such as learning and memory. Given that some HATs are directly involved in these processes, and that loss of HAT activity has been described in neurodegenerative disease, the development of specific HAT/HDAC modulators is an exciting area for future research.

HDAC8 antibody (GTX113981)
WB analysis with HDAC8 antibody on mouse brain tissue.

HDAC11 antibody (GTX116403)
IHC-P analysis with HDAC11 antibody on H1299 xenograft.

Histone Modifying Enzymes - Methylation

Like acetylation, methylation of histones is a fundamental epigenetic mechanism to establish, maintain, or alter the phenotypic identity of a eukaryotic cell. Histone methylation occurs primarily on lysine and arginine residues, and can often take the form of mono-, di-, or tri-methylated variants. Much interest has been directed to the specific lysine methylation events on histone H3, as individual methylation sites are associated with distinct effects on gene expression. Methylation is somewhat unique among the histone modifications, as particular methylation events affect other chromatin-based functions even beyond transcriptional regulation, including DNA replication, heterochromatin formation, alternative splicing, recombination, DNA repair, and cell cycle control. The orchestration of a cell's histone methylation profile relies on the activities of a large number of histone methyltransferases and demethylases. Though not yet definitive, there is increasing evidence that dysregulation of the activities of these enzymes may contribute to various cancers and neurologic disorders. The challenge for the future is to further identify and characterize how these factors impact human disease.
